This is a fun chat and story creation app that I built. It's designed for writers, roleplayers, and anyone who wants to create, edit, and export multi-character conversations with rich formatting and media support.

[Sidebar & Theme] On the left, you'll see the sidebar. Here, you can quickly switch between different color themes to match your style. Just pick a theme from the dropdown, and the whole app updates instantly.

[Adding Users & Characters] You can add new users and characters with just a click. Enter their names, and they'll appear in your character list. You can also upload custom avatars, change their font style, color, and even the font family for each character, making every conversation unique.

[Importing & Exporting Chats] If you have an existing chat (preferably exported from this app for LLM user/character compatibility), you can load it right here. The app supports .txt, .docx, and .json files. Just select your file, and your chat will appear, ready to edit or continue. (You can also exported SillyTavern chats in .txt format).

When you're done, you can export your chat in several formats: HTML for web, TXT for plain text, DOCX for Word, or JSON for backup and sharing.

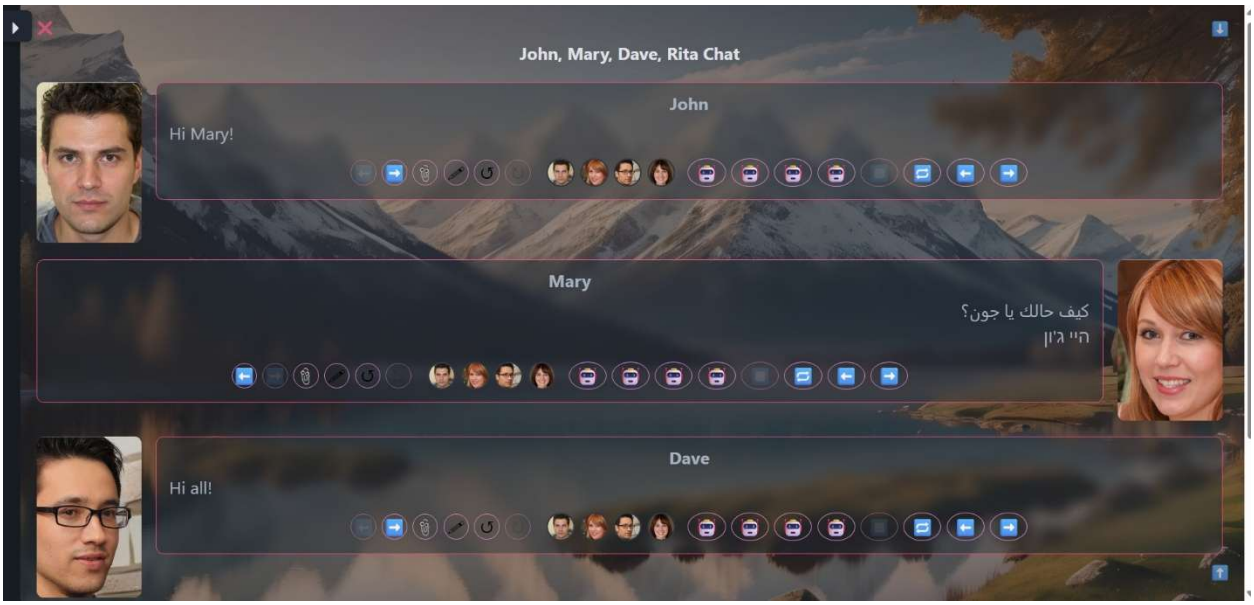
Exporting the chat in .json format preserves all the layout format, user, characters, pinned media, and LLM presets. When that file imported again, you won't lose any adjustments you made before you export it.

[Chat Title & Layout] You can set a custom chat title, or let the app generate one for you. There are also layout controls—adjust the message box width, font size, portrait size, and even the shape of character portraits. You can tweak the blur effect for messages, and reset any setting with a single click.

[Colors & Customization] Want to personalize further? Change the main text color, the border and quote color, and the color for italic or character names. All of this is just a click away.

[Main Chat Area] In the main area, you'll see your conversation. Each message shows the speaker's name and avatar. You can add, edit, or delete messages, and even attach images or videos to any message.

Here are the functions available at the lower row of each message:



- Left-to-Right writing direction LTR
- Right-to-Left writing direction RTL
- Media Attach
- Edit Message
- Undo Edit
- Redo Edit
- Add New Message for displayed User/Character
- Generate LLM Message for displayed User/Character(s), hover over the robot icon to see the user/character name, they are aligned in the same order as the user/character(s) avatars.
- Regenerate last message (LLM)
- Swipe left for the previous generated LLM message (stops at the first generated message).
- Swipe right for next generated LLM message (stops at the last generated message).

When Message is in Edit mode (click inside a message to edit its content)

- Same as above with these additions
- Save Edits (fourth icon)
- Cancel Edits (fifth icon)
- Delete message (six icon)

[Media Drag & Resize] One of the cool features is media (image/video) attaching and handling. You can drag and resize attached images or videos (resize and drag does not work in mobile browser).

[AI Presets & LLM Integration] For advanced users, there's a section for AI presets. You can import or export LLM (Large Language Model) settings, adjust memory, response length, temperature, and more. This is great for customizing how AI responds in your chats.

P.S: I manually entered the presets the first time and exported the presets as .json (I imported several published all-in-one presets, but that didn't import into the LLM Presets).

P.S: For LLM Generation:
- server.js must be running (open the program directory /src, open a command window then run node server.js)
- Koboldcpp must be running at port: 5001.

[Backgrounds & Settings] You can set a custom background image for your chat, or remove it anytime.

[Mobile browser] You can access the program with all its features in your mobile browser (http://yourpcip:3000) All the features (inserted media drag and resize does not work).
P.S: server.js must be running (open the program directory /src, open a command window then run node server.js)
P.S: For LLM, Koboldcpp must be running at port: 5001.

That's a quick tour of the app! It's meant for creative storytelling, roleplay, or just fun conversations. Your feedback is welcomed!
